

A Group Recommendation System for Music Using Implicit User Feedback

Te Lan (he/him)

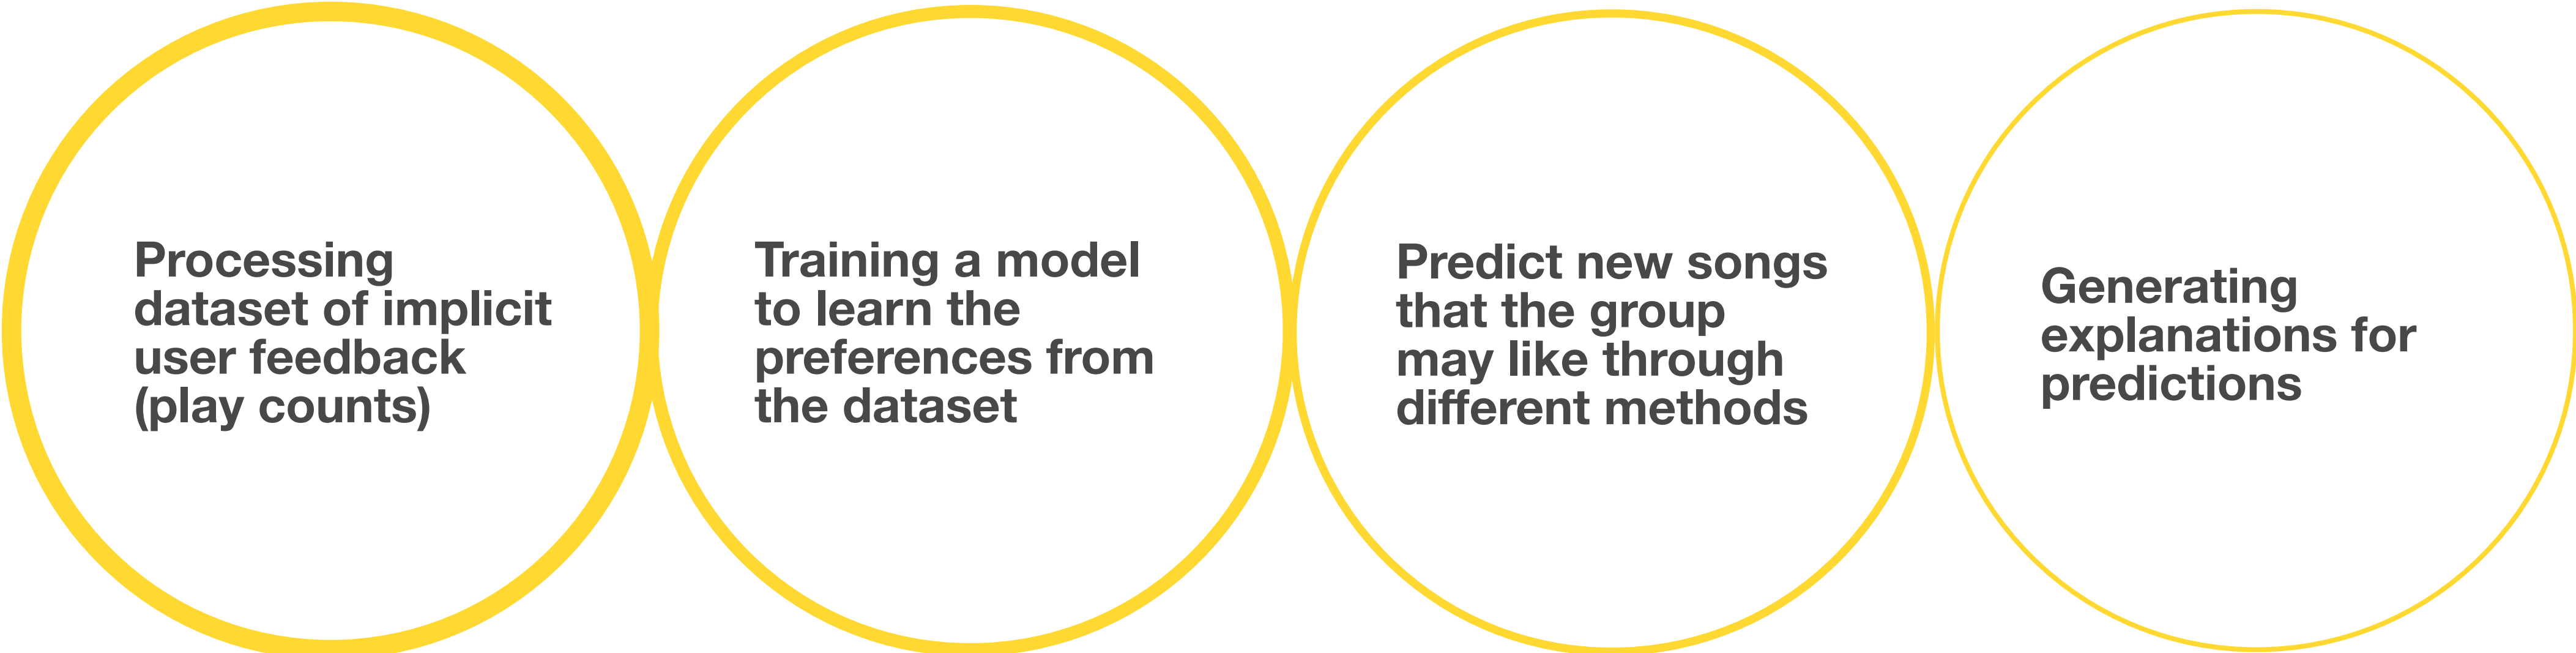

MSc Data Science & AI for the Creative Industries

2022

A system recommending songs to a group of people at events

e.g. dinner parties, small
gatherings, team-buildings...

```
graph LR; A((Processing dataset of implicit user feedback (play counts))) --- B((Training a model to learn the preferences from the dataset)); B --- C((Predict new songs that the group may like through different methods)); C --- D((Generating explanations for predictions));
```

**Processing
dataset of implicit
user feedback
(play counts)**

**Training a model
to learn the
preferences from
the dataset**

**Predict new songs
that the group
may like through
different methods**

**Generating
explanations for
predictions**

Technical challenges

1

Implementing implicit user feedback to an algorithm designed for explicit user feedback

Unfortunately, the majority of the work in matrix factorization is centered on high-quality explicit feedback datasets, in which users make their preferences known by directly rating subsets of accessible items on a fixed scale (Hu et al., 2008). However, these explicit ratings are not available in many real-world situations.

2

Assessing different group recommendation methods on new dataset

The group recommendation approaches can be roughly differentiated into two, the Pseudo-user approach (Kim and Lee, 2014) and the Consensus approach (Villavicencio et al., 2016; Kim and El Saddik, 2015).

3

Generating explanations for recommendations

It is acknowledged that explainability is essential between Human-AI interaction for the purpose of enhancing people's understanding of the system and building trust (Q. Vera et al, 2021).

Discussion

Converting play count data to rating data work is **practicable** for recommendation algorithm using Matrix Factorisation based Collaborative Filtering.

The precision rates using AF method is **significantly higher in all three group sizes**, with the best performance (precision = 0.729881) for medium size groups (n=5).

Explanations can be generated after the recommendation is performed. “Top influencers for the playlist” informs the representation of every group member in the playlist, “Likely enjoyed by...” tells why a song is recommended.

Discussion continues..

User trust and clarity

Factors and bias of group profile and group members, an example from a medium size group using AF method

Conclusions

- 01** Utilising implicit user feedback like play counts by converting to ratings is practical given the limits of obtaining explicit user feedback real world.
- 02** The after factorisation method (AF) is proven to perform the best for all group sizes between three to ten people.
- 03** We can generate explanation to inform the reason for every suggested music as well as how much every group member is represented in the playlist.

Future work

Modifying the evaluation method

Applying a larger dataset

Optimising the sampling process.

User test that draw on how the
explanation affect the mental model
in users

It is acknowledged that explainability is essential between Human-AI interaction for the purpose of enhancing people's understanding of the system and building trust (Liao et al, 2021).

Thank you
